

## Friedmann-Lemaître cosmological solutions

Experimental evidence :

Hubble, Humason 1927

- The universe is and has been expanding.
- It appears to be spatially essentially isotropic and homogeneous on scales larger than a few (3-4) million light years.

↑  
(see e.g. Sloan Digital Sky Survey (SDSS))  
at [www.sdss.org](http://www.sdss.org))

Idealizing models:

- Assume perfect spatial isotropy and homogeneity :
- ↳ "Friedmann & Lemaître" (later Robertson & Walker) spacetimes

Concretely:

We assume we can model spacetime as a manifold  $(M, g)$  with:

$$\begin{aligned} M &= \mathbb{J} \times \Sigma \\ g &= -dt^2 + a^2(t)\bar{g} \end{aligned}$$

(we will later  
use an ON frame  
so that  $g_{\mu\nu} = g_{\nu\mu}$ )

↑ In the basis  $\{\partial_t, \partial_\Sigma\}$  which comes  
with the coordinate system.

Here:

- $\mathbb{J}$  is an interval,  $\mathbb{J} \subset \mathbb{R}$ , and  $t \in \mathbb{J}$  is called "cosmic time".  $a(t)$  is called the "scale factor".
- $(\Sigma, \bar{g})$  is a fully isotropic & homogeneous Riemannian manifold, i.e., a manifold of constant curvature, providing a 3-dim. surface of homogeneity at each point in cosmic time.

## What are the possible Riemannian manifolds of constant curvature?

→ bar for Riemannian mfd of 3 dim.

□ The Riemann tensor  $\bar{R}_{ij\bar{k}\bar{l}}$  must be expressible in terms of a constant, say  $K$ , which fixes the curvature's strength, and the tensorial part can only depend on the metric  $\bar{g}$ .

⇒ Given the index symmetries of  $\bar{R}_{ij\bar{k}\bar{l}}$  → it should (and does) take the form:

$$\bar{R}_{ij\bar{k}\bar{l}} = K \left( \bar{g}_{i\bar{k}} \bar{g}_{j\bar{l}} - \bar{g}_{i\bar{l}} \bar{g}_{j\bar{k}} \right) \quad (\star)$$

$$\Rightarrow \bar{R}_{ij} = 2K \bar{g}_{ij}, \bar{R} = 6K$$

⇒ Using a "Triad"  $\{\bar{\theta}^i\}$ : curvature 2-form on  $\Sigma$

$$\bar{\Omega}_{ij} \stackrel{\text{Def.}}{=} \frac{1}{2} \bar{R}_{ij\bar{k}\bar{l}} \bar{\theta}^k \wedge \bar{\theta}^l \stackrel{(\star)}{=} K \bar{\theta}_i \wedge \bar{\theta}_j$$

(ON bases of  $T_p(\Sigma)$ ,  $\nu_p$ )

### Role of the signature of $K$ :

Note: 4-dim pseudo-Riemannian manifolds with constant curvature are called "de Sitter universes".

$K > 0$ : ⇒  $\Sigma$  is a 3-dim. sphere (that can be embedded e.g. in a 4-dim euclidean (i.e. flat) space : closed universe

$K = 0$ : ⇒  $\Sigma$  is euclidean  $\mathbb{R}^3$ . flat, infinite universe

$K < 0$ : ⇒  $\Sigma$  is a 3-dim. "pseudo sphere". The constant negative curvature means it is everywhere "like a saddle". These  $\Sigma$  also possess  $\infty$  volume.

□ Note:  $\bar{R}$  and therefore  $K$  have units  $\frac{1}{(\text{length})^2}$ . Thus, by suitable choice of unit of length, we can choose units of length so that: (This is usually done in cosmology)

$$K = -1, 0 \text{ or } 1$$

A tetrad for spacetime:  $g = -dt^2 + a^2(t)\bar{g}$

□ Define a convenient tetrad, i.e., ON basis of each  $T_p(M)$ :

$$\theta^0 := dt$$

with  $t = \text{cosmic time of above}$

$$\theta^i := a(t) \bar{\theta}^i$$

with  $\bar{\theta}^i$  being the triad of  $\Sigma$

□ Note: The  $\bar{\theta}^i$  were chosen ON with respect to  $\bar{g}$ .

The  $\theta^i$  are ON with respect to  $g$ .

We then have, e.g.:

\* 1st structure equation on  $\Sigma$ :  $\check{\square} \quad (i,j=1,2,3)$

Recall:

The Cartan structure equations

express the torsion and curvature

forms in terms of the connection form.

(6 eqns:  $\Omega^k_j = dw^k_j + w^i_k \omega^j_i$ )

$$d\bar{\theta}^i + \bar{\omega}^i_j \lrcorner \bar{\theta}^j = 0 \quad (\Sigma 1)$$

\* 1st structure equation on  $M$ :  $\check{\square} \quad (\nu,\mu=0,1,2,3)$

$$d\theta^\nu + \omega^\nu_\mu \lrcorner \theta^\mu = 0 \quad (M 1)$$

Determine the 4-connection  $w^\nu_\mu$ : (in spatially isotropic & homogeneous case)

Strategy: Calculate  $d\theta^i$  in two ways:

$$1.) \quad d\theta^i = d(a\bar{\theta}^i) = (da) \lrcorner \bar{\theta}^i + \underbrace{a d\bar{\theta}^i}_{\text{use Eq. } \Sigma 1}$$

$$= \left( \frac{da}{dt} dt \right) \lrcorner \bar{\theta}^i - a \bar{\omega}^i_j \lrcorner \bar{\theta}^j$$

$$(\text{use } a\bar{\theta}^i = \theta^i) \Rightarrow = \dot{a} \theta^0 \lrcorner \bar{\theta}^i - \bar{\omega}^i_j \lrcorner \theta^j$$

$$\left( \begin{array}{l} \text{use } \bar{\theta}^i = \frac{1}{a} \theta^i \\ \text{and } \theta^i \lrcorner \theta^0 = -\theta^0 \lrcorner \theta^i \end{array} \right) \Rightarrow = -\frac{\dot{a}}{a} \theta^i \lrcorner \theta^0 - \bar{\omega}^i_j \lrcorner \theta^j \quad (A)$$

$$2.) \quad d\theta^i = -\omega^i_\nu \lrcorner \theta^\nu = -\omega^i_0 \lrcorner \theta^0 - \omega^i_j \lrcorner \theta^j \quad (B)$$

Compare eqns A,B  $\Rightarrow$

$$\omega^i_0 = \frac{\dot{a}}{a} \theta^i \quad \text{and} \quad \omega^i_j = \bar{\omega}^i_j \quad (\text{Box})$$

(Intuition: expansion is nontrivial affine connection between space and time.)

What is  $w^0_0$ ? Recall:

$$d\eta_{\mu\nu} = \omega_{\mu\nu} + \omega_{\nu\mu}$$

But  $d\eta_{\mu\nu} = 0$  for ON frames.

Thus  $\omega_{\mu\nu} = -\omega_{\nu\mu}$  here.

$$\Rightarrow \omega_{00} = 0$$

## The curvature 2-form:

Recall: 2nd structure equations: (analogous to:  $R_{\mu\nu} = \Gamma_{\mu\nu} + \Gamma_{\mu\lambda}\Gamma^{\lambda}_{\nu} + \Gamma_{\nu\lambda}\Gamma^{\lambda}_{\mu}$ )

$$\Omega^r_v = d\omega^r_v + \omega^r_g \wedge \omega^g_v \quad (M2)$$

$$\bar{\Omega}^i_j = d\bar{\omega}^i_j + \bar{\omega}^i_e \wedge \bar{\omega}^e_j \quad (\Sigma 2)$$

$$\Rightarrow \begin{aligned} \Omega^i_j &= d\omega^i_j + \omega^i_r \wedge \omega^r_j \\ &= d\bar{\omega}^i_j + \bar{\omega}^i_e \wedge \bar{\omega}^e_j + \omega^i_o \wedge \omega^o_j \\ &\stackrel{\Sigma 2}{=} \bar{\Omega}^i_j + \omega^i_o \wedge \omega^o_j \end{aligned}$$

for  $i, j \in \{1, 2, 3\}$  (afterwards we will calculate  $\Omega^o_i, \Omega^o_o$ )  
use (Box)  $\Rightarrow$

Recall also:

$$\bar{\Omega}^{ij} = K \bar{\theta}^i \wedge \bar{\theta}^j = \frac{K}{a^2} \theta^i \wedge \theta^j \quad (\text{It was a consequence of spatial isotropy \& homogeneity})$$

$$\Rightarrow \Omega^{ii} = \frac{K}{a^2} \theta^i \wedge \theta^i + \frac{\dot{a}^2}{a^2} \theta^i \wedge \theta^i \quad \left\{ \begin{array}{l} \text{Recall from equations (box):} \\ w^o_i = \frac{i}{a} \dot{a}^i, \quad w_{oi} = -\frac{a}{\dot{a}} \dot{a}^i \\ w_{io} = \frac{a}{\dot{a}} \dot{a}^i, \quad w^i_o = \frac{i}{a} \dot{a}^i \end{array} \right.$$

$$\Rightarrow \boxed{\Omega^{ii} = \frac{K + \dot{a}^2}{a^2} \theta^i \wedge \theta^i}$$

Similarly, one calculates: Exercise: check

$$\boxed{\Omega^{oi} = \frac{\ddot{a}}{a} \theta^o \wedge \theta^i}$$

Calculate the Einstein tensor:

Recall:  $\Omega_{\mu\nu} = \frac{1}{2} R_{\mu\nu\sigma\tau} \theta^\sigma \wedge \theta^\tau$

$\Rightarrow$  We can read off  $R_{\mu\nu\sigma\tau}$ .

$\Rightarrow$  We obtain the Ricci tensor  $R_{\mu\nu}$  and the curvature scalar  $R$ .

$\Rightarrow$  We obtain the Einstein tensor:

$$G_{\mu\nu} = R_{\mu\nu} - \frac{1}{2} g_{\mu\nu} R$$

Result:

$$G_{00} = 3 \left( \frac{\dot{a}^2}{a^2} + \frac{K}{a^2} \right)$$

Exercise: verify

$$G_{ii} = -2 \frac{\ddot{a}}{a} - \frac{\dot{a}^2}{a^2} - \frac{K}{a^2}$$

$$G_{\mu\nu} = 0 \text{ for } \mu \neq \nu$$

i.e.,  $G_{\mu\nu}$  is diagonal in this frame.

The energy-momentum tensor:

From  $G_{\mu\nu} = 8\pi G T_{\mu\nu}$

we obtain that  $T_{\mu\nu}$  must also be diagonal.

Recall the interpretation of the entries of a diagonal  $T_{\mu\nu}$  in terms of matter energy density  $\rho$ , matter pressure  $p$  and cosmological constant  $\Lambda$  at the origin of geodesic coordinates:

$$T_{\mu\nu} = \begin{pmatrix} \rho & 0 \\ 0 & p \\ 0 & p \\ 0 & p \end{pmatrix} - \frac{1}{8\pi G} \Lambda \begin{pmatrix} -1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}$$

Why this factor here?  
Because  $\Lambda$  was traditionally put on the LHS, with the curvature

$\Rightarrow$  The only nontrivial dynamics of matter is here its equation of state:

$$\rho = \rho(p) \quad !$$

What kind of matter causes such a  $T_{\mu\nu}$ ?

Proposition:

The  $T_{\mu\nu}$  of any F.L. spacetime is always of the form of that of a perfect fluid.

\* The matter doesn't have to be fluid - it could also be e.g. a suitable quantum field.

\* But the high symmetry of a F.L. spacetime requires that the matter's  $T_{\mu\nu}$  matches that of a perfect fluid.

Proof: Consider the 4-vector field dual to  $\Theta^\circ$ :

$$u = \frac{\partial}{\partial t} = e_0, \text{ i.e.: } u = u^\nu e_\nu \text{ with } u^0 = 1, u^i = 0.$$

Using  $u$ ,  $T^{\mu\nu}$  takes the form that characterizes a perfect fluid:

$$T^{\mu\nu} = (g + p) u^\mu u^\nu + (\rho - \bar{\Lambda}) g^{\mu\nu}$$

Q: If the matter is a fluid, what's the vector field  $u$ ?

A:  $\downarrow$  i.e. our galaxy  
Recall: We are a particle of the fluid and  $u$  is our velocity:

Why?  $u$  is tangent to timelike geodesics (that stand still in space)  
(because  $u \perp e_i \forall i=1,2,3$ )

$$\nabla_u u = \nabla_{e_i} e_0 = \omega^{\nu}_{\ 0} (e_i) e_\nu = \frac{\alpha}{a} \theta^i (e_i) e_i = 0$$

## The Einstein equation:

$$G_{\mu\nu} = 8\pi G T_{\mu\nu}$$

now consists of:

$$G_{00} = 8\pi G T_{00} \Rightarrow$$

$$3 \left( \frac{\dot{a}^2}{a^2} + \frac{k}{a^2} \right) = 8\pi G s + \Lambda$$

"Friedmann equation" (A)

$$G_{cc} = 8\pi G T_{cc} \Rightarrow$$

$$-2 \frac{\ddot{a}}{a} - \frac{\dot{a}^2}{a^2} - \frac{k}{a^2} = 8\pi G p - \Lambda$$

(B)

□ Notice that  $\Lambda$  contributes

- positively to the energy but
- negatively to the pressure.

Observation:  $k/a^2$  occurs in (A) and (B), i.e., we can eliminate it:

$$-\frac{1}{2} a \left( \text{Eqn(B)} + \frac{1}{3} \text{Eqn(A)} \right) \text{ yields:}$$

$$\ddot{a} = -\frac{1}{2} a 8\pi G \left( \frac{s}{3} + p \right) - \frac{1}{2} a \Lambda \left( -1 + \frac{1}{3} \right)$$

⇒

$$\ddot{a} = -\frac{4\pi G a}{3} (s + 3p) + \frac{1}{3} a \Lambda$$

Thus for all  $k$ : For ordinary matter must have deceleration, i.e.,  $\ddot{a} < 0$ , but a positive cosm. constant  $\Lambda$  can make  $\ddot{a} > 0$ .

## Experimental evidence?

- Supernova distance versus brightness data and evidence from cosmic background radiation:

$\ddot{a} > 0$  now!

$\Rightarrow$  At present, energy is already sufficiently diluted

Note:  $\rho$  of a gas of galaxies is negligible.

Note:  $S$  includes dark matter.

Visible matter is only  $\approx 3\%$ .

so that  $\Lambda$  dominates over  $S$ :  $\approx 70\%, \Lambda$  and  $\approx 30\% S^{\text{matter}}$  (dark + visible)

- In the far future,  $S$  &  $\rho$  will have diluted  $\rightarrow 0$ ,

Or something other than  $\Lambda$  will dominate  $T_{\mu\nu}$  then.

Experiments indicate that indeed a faster than exponential expansion may be underway. That cannot come from just  $\Lambda$  dominance alone. See essay topic!

leaving only  $\Lambda$ . Then, the Friedmann eqn reads:

$$3 \left( \frac{\dot{a}^2}{a^2} + \frac{k}{a^2} \right) = \Lambda$$

Solutions:

$$a(t) = \begin{cases} \cosh(t\sqrt{\frac{\Lambda}{3}}) & \text{for } K=1 \\ \exp(t\sqrt{\frac{\Lambda}{3}}) & \text{for } K=0 \\ \sinh(t\sqrt{\frac{\Lambda}{3}}) & \text{for } K=-1 \end{cases}$$

$\Rightarrow$  Exponential expansion is predicted!

## General solution strategy with cosm. constant and matter:

- We have 3 unknown functions of time

$$a(t), S(t), \rho(t)$$

and we have 3 equations that they obey:

Eqs. A, B and an equation of state  $p=p(S)$  that depends on the "matter":

$$P_n(S) = -S_n \quad \text{for pure vacuum energy} \quad (\text{e.g., in very early universe})$$

$$P(S) = \frac{1}{3}S \quad \text{for pure radiation} \quad (\text{e.g., in the early universe})$$

$$P(S) = 0 \quad \text{for pure dust} \quad (\text{e.g., middle aged universe before } \Lambda \text{ took over})$$

## Observation:

(Eqn. A)

The Friedmann eqn. only contains  $a, S$  but not  $\rho$ !

Idea:

this models the dilution of energy density

- Try to express  $\dot{S}$  as a function of  $a$  to obtain:  $\dot{S} = S(a)$ .
- Using  $S(a)$ , the Friedmann eqn becomes an ordinary differential equation only for  $a(t)$  and we are done!

Indeed, a key equation helps us to find  $S(a)$ :

Proposition: The Einstein eqns A, B, i.e.,  $G_{\mu\nu} = 8\pi G T_{\mu\nu}$ , imply:

$$\frac{d}{da} (S a^3) = -3 \rho a^2 \quad (\text{P})$$

Indeed, when the parameter  $w$  in  $\rho = wS$  is known, (P) yields  $S(a)$ :

□ For dust,  $\rho = 0 \Rightarrow S \sim a^{-3}$

□ For radiation,  $\rho = S/3 \Rightarrow S \sim a^{-4}$

□ For pure  $\Lambda$ :  $\rho = -S \Rightarrow S = \text{const}$

$S$  of radiation decays quicker than  $S$  of dust because radiation is not only diluted, its wavelengths are also stretched, which reduces the energy too.

Intuitive meaning of (P)?

□ (P) is the GR version of the continuity equation for  
(i.e., without heat exchange)  
with an environment  $\rightarrow$  adiabatic expansion:  $dE = -\rho dV$

□ With  $V = a^3$ ,  $E = S V$  it yields:

$$d(a^3 S) = -\rho d(a^3) = -3 \rho a^2 da$$

□ Thus:  $\frac{d}{da} (a^3 S) = -3 \rho a^2$  which is indeed (P).

## Exact proof of proposition (P):

□ The Einstein equation  $G^{\mu\nu} = 8\pi G T^{\mu\nu}$  and  $G^{\mu\nu}_{;\nu} = 0$  imply  $T^{\mu\nu}_{;\nu} = 0$

□ Here:  $T^{\mu\nu} = (\rho + p) u^\mu u^\nu + p g^{\mu\nu}$

□ Thus:

$$0 = T^{\mu\nu}_{;\nu} = \underbrace{(\rho_{;\nu} + p_{;\nu}) u^\mu u^\nu + (\rho + p) u^\mu u^\nu_{;\nu}}_{\text{Leibniz rule}} + p_{;\nu} g^{\mu\nu} \quad (g^{\mu\nu}_{;\nu} = 0)$$

(using  $\nabla_{\mu\nu} w = \nabla_\mu w \Rightarrow u^\mu \nabla_\nu u^\nu = \nabla_\mu u^\nu$ )

$$= (\nabla_\mu \rho + \nabla_\mu p) u^\mu + (\rho + p) u^\mu \nabla_\mu u^\nu + p_{;\nu} u^\nu \quad | \cdot u_\mu$$

(using  $u^\mu u_\mu = 1$ )  $\Rightarrow$

$$= -\nabla_\mu \rho - \nabla_\mu p - (\rho + p) \nabla_\mu u^\nu + u_\mu p_{;\nu}$$

$$\Rightarrow 0 = \nabla_\mu \rho + (\rho + p)(\nabla_\mu u^\nu) \quad (X)$$

It remains now to calculate  $\nabla \cdot u$ :

$$\begin{aligned} \nabla \cdot u &= u^\lambda_{;\lambda} = \theta^\lambda (\nabla_{e_\lambda} e_0) \\ &= \theta^\lambda (\underbrace{\omega^c_0(e_\lambda)}_{\text{numbers}} e_c) = \omega^{\lambda}_0(e_\lambda) = \omega^i_0(e_i) \\ &= \frac{\dot{a}}{a} \theta^i(e_i) = 3 \frac{\dot{a}}{a} \end{aligned}$$

Recall:  $\nabla_g e_b = \omega^c_b(g) e_c$   
*i.e.*:  $\nabla_{e_a} e_b = \omega^c_b(e_a) e_c \Rightarrow$

↑ and  $\theta^i(e_i) = \delta^i_i$

↑ since  $\omega^0_0 = 0$

$\Rightarrow$  Eqn. (X) becomes:

$$\nabla_\mu \xi \overset{?}{=} \dot{\rho} + 3 \frac{\dot{a}}{a} (\rho + p) = 0 \quad (\text{Recall: } u = \frac{d}{dt})$$

Thus:

$$\dot{\xi} \frac{a^3}{a} + 3(\rho + p)a^2 = 0$$

$$\frac{d\xi}{da} \frac{a^3}{a} + 3\rho a^2 = -3pa^2$$

$$\frac{d\xi}{da} a^3 + 3\rho a^2 = -3pa^2$$

$$\Rightarrow \boxed{\frac{d}{da} (\rho a^3) = -3pa^2}$$

this is Eqn (P) ✓
